

# Rock glacier

## Comment:

Debris landform generated by permafrost creep, detectable in the landscape with a front (discernable talus delimiting the terminal part of the moving area perpendicularly to the principal flow direction), lateral margins in continuity of the front and often ridge-and-furrow surface topography.

An active rock glacier (as illustrated) is currently conveying debris from an upslope area (rooting zone) towards its front.

Vallone di Sort, Italy  
45.5605°N, 7.1589°E  
2500-2800 m.a.s.l.

No scale (oblique view). Rock glacier length is about 500m
